R: En este modelo obtenemos un $R^2 = 0.0516 \sim 0.05$ indicando que el modelo explica solo un 5% de la variación de la expectativa de vida ("expectancy"). Esto es esperable, ya que la respuesta a esta variable es bastante subjetiva, dependiendo de factores no observables como salud mental, que tan optimista es, apoyo familiar, etc.

A pesar del R^2 bajo, todos los coeficientes son estadísticamente significativos ($p<0.05$). Por ejemplo tenemos la variable "edu" con un coeficiente de 0.066 positivo, indicando que el aumento de 1 año de educación incrementa en promedio 0.066 años (~24 días) en la expectativa de vida. Este valor positivo es lo esperado ya que una mayor educación está relacionada con mejores hábitos y mayor acceso a salud.

wage con coeficiente positivo (7.142e-07) dado que ese valor representa el aumento en expectavida de vida cuando aumenta en 1 peso. Esta magnitud positiva puede deberse a mejor calidad de vida y flexibilidad economica ante cualquier complicación de salud.

Por otro lado tenemos el parametro "cronica_1.0" que representa si tiene enfermedidad crónica es significativo pero tiene un coeficiente de 0.7417 positivo, indicando que la presencia de una enfermedad cronica incrementa 0.7417 años la expectativa de vida. Este valor positivo no es lo esperado, ya que el tener una enfermedad de este tipo puede representar dificultades para el día a día de las personas. Sin embargo los otros parametros "illness_1.0" y "mental_1.0" poseen valores negativos, lo que seria lo esperado.

También tenemos la variable de "status" que representa si el individuo está casado, convive, está divorciado, está viudo o está soltero. De los resultados podemos notar que el unico "status" positivo es el "status_viudo".

Por ultimo tenemos los time que dejando de lado sus coeficientes negativos notamos una tendencia a que a medida que aumentan las rondas los coeficientes tienden al positivo, esto se puede deber a que como pasan los años para los individuos consecuentemente también aumentan su edad y por ende tienen mayores expectativas de vida, o también porque al paso del tiempo se descubren avances en salud.

3. Ejecute un modelo efectos fijos para estimar la misma relacion anterior. Seleccione las variables independientes a incluir en el modelo final e interprete su significado.

F-test for Poolability: 1.8518
P-value: 0.0000
Distribution: F(19070,17939)

Included effects: Entity
```

R: obtenemos un R^2 de 0.0306 indicando que representa un 3.06% de la varianza de los datos. A diferencia del modelo Pooled OLS obtenemos que el p-value de varias variables cambia drasticamente dejando de ser significativas en algunos casos como: "edu", "wage","hours","cronica_1.0" entre otras con p-value = 0.4095, 0.9133, 0.8361, 0.5603 respectivamente. Esto se puede deber a que el modelo Pooled OLS contenga sesgo de variables no observadas emitidas ya que no considera diferencias sistematicas entre los individuos. A diferencia del modelo de efectos fijos FE que si controla esto. Sin embargo aquí observamos que ahora los parametros "edu" y "wage" poseen coeficientes negativos, lo que es contratuitivo, en especial por el lado de "wage" que debiera significar una mayor expectativa de vida a medida que se posee mayor flexibilidad economica.

Por otro lado en este modelo "cronica_1.0" si posee un coeficiente negativo que si es lo esperado. Y de esta forma también cambian de sentido otros coeficientes.

Time se comporta de la misma manera que en Pooled OLS.

4. Ejecute un modelo de efectos aleatorios para estimar la misma relacion anterior. Seleccione las variables independientes a incluir en el modelo final e interprete su significado.

R: En en este modelo obtenemos un R^2 general de 0.4055 significando que representa un 40.55% de la variación en la expectativa de vida es explicada por las variables independientes. Este considerable porcentaje se puede deber a que el modelo RE aprovecha tanto la variación dentro del individuo (a lo largo de las rondas) y la variación entre individuos, lo que hace explicar más varianza de los datos que el modelo de efectos fijos FE. Al igual que en el modelo Pooled OLS se observa que todas las constantes son significativas, sin embargo esto se puede deberse a que existe correlación entre variables no observadas y las variables independientes generando sesgo en los coeficientes estimados.

Time se comporta de la misma manera que en los modelos anteriores.

```
Effects                   30.828178
Residual                  69.679212
Percent due to Effects     0.306725
Name: Variance Decomposition, dtype: float64
```

5. Comente los resultados obtenidos en 2, 3 y 4. ¿Cuáles y por qué existen las diferencias entre los resultados?. En su opinión, ¿Cuál sería el más adecuado para responder la pregunta de investgación y por qué? ¿Qué variables resultaron ser robustas a la especificación?

R: En cuanto al modelo Pooled OLS, este asume que no existen diferencias entre invidivuos ni efectos no observados, lo cual no se adecua para nuestros datos de panel. Al no considerar esta estructura, entregó estimaciones segadas dada la correlación mencionada anteriormente.

Luego analizando los modelos de efectos fijos y aleatorios realizamos un Test de Hausman donde obtenemos un p-value $\sim 0 < 0.05$ lo que nos lleva a rechazar la hipótesis nula que favorece utilizar el modelo de efectos aleatorios. Este resultado indica que existe correlación entre efectos individuales no observados y las variables dependientes, es decir que los factores individuales no observados afectan tanto a la variable dependiente ("expectancy") como a las independientes (X).

Los resultados diferentes se deben a esta correlación existente y no controlada en el modelo Pooled OLS y efectos aleatorios, que sesga las estimaciones otorgando significancias y coeficientes incorrectos.

Por lo tanto es mas adecuado utilizar un modelo de efectos fijos para responder la pregunta de investigación incluso si explica menos varianza total, ya que controla las diferencias indivuales, eliminando el sesgo.

En cuanto a las variables que resultaron ser robustas a la especificación tenemos "hours", "status_convive", "status_divorciado", "kids_1", "illnes_1.0", "mental_1.0", "time_2.0", "time_3.0" y "time_4.0"

6. Ejecute un modelo de efectos aleatorios correlacionados (CRE) para estimar la misma relacion anterior. Seleccione las variables independientes a incluir en el modelo final e interprete su significado. Es este modelo adecuado, dada la data disponible, para modelar el componente no observado?

```

R: De este modelo obtenemos que existen 19071 individuos únicos, con un promedio = 1.94 de observaciones por individuo.

Del modelo se obtuvo un R^2 (Within) = 0.0284 indicando que el modelo explica un 2.84% de la variabilidad de los datos dentro de cada individuo, esto puede ser que al ser un par de años de diferencia entre cada ronda (time) de la encuesta el individuo no cambie mucho y se mantenga constante al largo plazo y como hay pocos cambios las variables explicativas tampoco tienen mucho que explicar.

Por otro lado obtenemos que el R^2 (Between) = 0.0597 indica que el modelo explica un 5.97% de la variabilidad de los datos entre individuos sin embargo se logran capturar parametros significativos entre los promedios.

También tenemos un R^2 (Overall) = 0.0499 que indica que el modelo explica un 4.99% de la variacion de los datos si fuera considerado como un OLS, no como tipo panel.

Finalmente tenemos R^2 = 0.4083 indicando que el modelo completo explica un 40.83% de la variación de los datos, lo que es un porcentaje considerable.

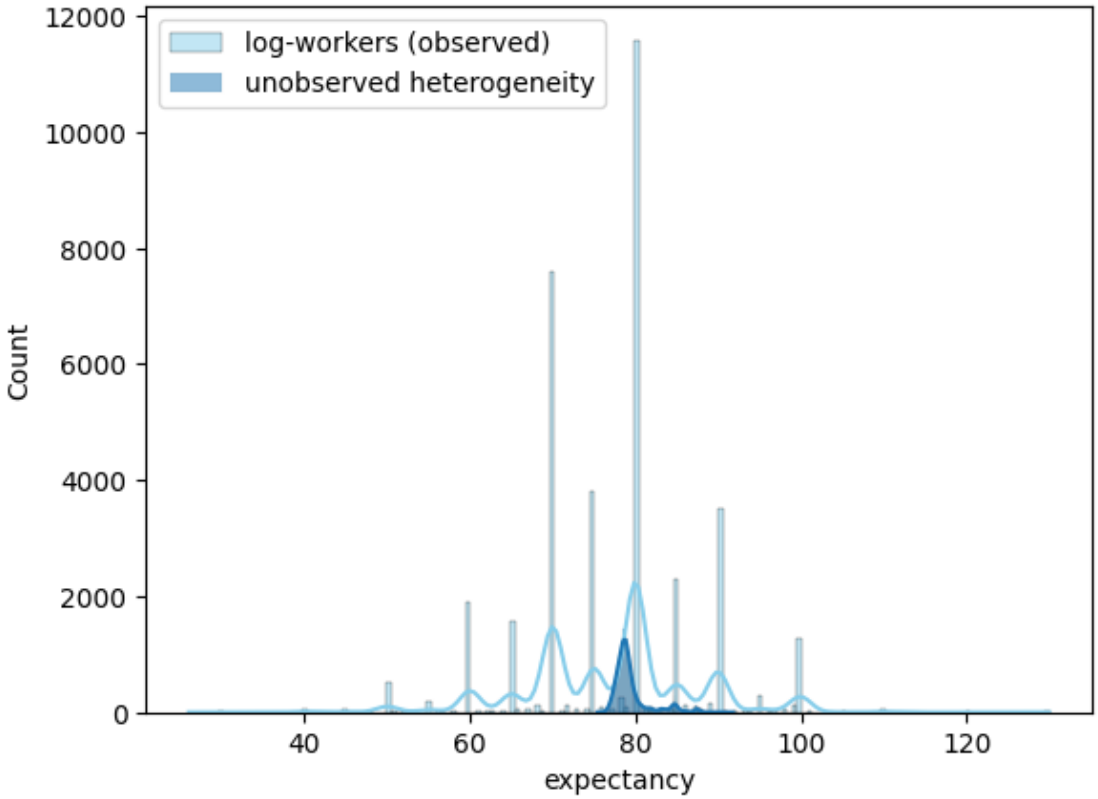
Respecto a observaciones interesantes en los coeficientes de los parametros tenemos que el coeficiente

“edu” es negativo y no significativo pero “medu” es positivo y si significativo, esto puede deberse a que “edu” analiza como cambia la expectativa de vida cuando aumentan los años de educación dentro de un individuo, y si es que la educación de un individuo varia muy poco en un par de años este no representa variación en la expectativa de vida. En cambio “medu” analiza la variación de los años de educación entre individuos donde si hay gran variación, ya que puede variar mucho de persona en persona, donde intuitivamente a mayor educación debería tener mayor expectativa de vida.

“hours” y “mhours” mantienen su signo negativo en ambos casos. Esto significa que tanto a nivel individual y a nivel entre individuos a mayor cantidad de horas trabajadas se tiene una expectativa de vida menor.

A pesar de que el modelo tiene bajo poder explicativo dentro y entre personas, tiene un poder explicativo decente para la variación de la data por lo tanto el enfoque CRE es adecuado para modelar el componente no observado dada la data disponible, ya que permite controlar la correlación entre los efectos no observados y las variables explicativas. Es importante para un panel como este donde los efectos fijos no serían estimables para muchos individuos ya que el promedio de observaciones por de individuo es 2 indicando que gran parte de los individuos tiene 1 o 2 observaciones, no permitiendo analizar adecuadamente como varia una persona a lo largo del tiempo.

7. Usando el modelo CRE, prediga la distribucion del componente no observado. Que puede inferir respecto de la heterogeneidad fija en el tiempo y su impacto en la expectativa de vida?



R: Usando el modelo CRE, podemos observar que la distribución del componente no observado sigue una forma similar a las expectativas de vida de los individuos, aunque levemente desplazada hacia la izquierda. Esto se puede deber a que el efecto no observado entre indiviudos que es representado por los promedios de las variables son principalmente coeficientes negativos.

8. Usando sus respuestas anteriores, que modelo prefiere? que se puede inferir en general respecto del efecto de las variables explicativas sobre la expectativa de vida?

R: Respecto a mis respuestas anteriores, prefiero el modelo CRE ya que mediante el test de Hausman determinamos que el modelo RE no es apto para nuestra data, por otro lado el modelo FE es apto pero representa un porcentaje muy bajo y el modelo Pooled OLS considera todos los individuos como una misma muestra, no distingue entre observaciones de diferentes individuos. El modelo CRE logra explicar un 40.83% de la varianza total y permite analizar tanto dentro de los individuos como entre individuos. Sin embargo en general se puede inferir que las variables explicativas no logran explicar correctamente la expectativa de vida de las personas. Esto se puede deber a que es una respuesta subjetiva, depende mucho de la mentalidad de la persona, su salud mental, circulo de apoyo, experiencias, etc.
